Declaration

I, **Soumili Dey** (Roll No. 241MT049), a 2nd year B.Tech student of the Department of Metallurgical and Materials Engineering, hereby declare that this project report entitled *"AI/ML-Driven Dashboard for Extractive Metallurgy Process Optimization"* has been prepared by me under the guidance of **Dr. S B Arya**.

The work presented in this report is original and has not been submitted elsewhere for the award of any degree or diploma.

Soumili Dey
241MT049
Date: April 4, 2026

Dr. S B Arya
(Faculty Supervisor)

Acknowledgement

I would like to express my sincere gratitude to **Dr. S B Arya**, Department of Metallurgical and Materials Engineering, for his valuable guidance and encouragement throughout this project. His insights on the intersection of artificial intelligence and metallurgical processes were instrumental in shaping this work.

I also thank the department for providing the computational resources and academic environment that made this project possible.

Soumili Dey

Abstract

Extractive metallurgy processes such as leaching, roasting, smelting, and flotation are governed by numerous inter-dependent parameters—temperature, pressure, pH, ore grade, reagent concentration, and residence time. Optimising these parameters manually is time-consuming and often sub-optimal.

This project presents an **AI/ML-driven interactive web dashboard** that integrates machine learning models and Large Language Model (LLM) APIs to (i) monitor real-time process metrics, (ii) predict metal recovery rates using trained regression models, (iii) generate process optimisation recommendations, and (iv) assess environmental impact.

The system is built using **React 18** with **Vite**, styled with **Tailwind CSS**, and visualised with **Recharts**. Recovery prediction leverages per-process **Linear Regression**, **Random Forest**, and **XGBoost** models trained on datasets for 10 metallurgical processes encompassing 200+ data points. The best models achieve $R^2 > 0.94$ across all processes, with Gold Cyanidation reaching $R^2 = 0.996$. AI-powered analysis is provided via the **OpenRouter API**, enabling natural-language process optimisation and environmental recommendations.

The dashboard demonstrates that AI/ML tools can meaningfully augment metallurgical decision-making, with estimated efficiency improvements of 3–5% and waste reduction potential of 20–30%.

Keywords: Extractive metallurgy, Machine learning, Recovery prediction, React dashboard, LLM integration, Process optimisation.

Chapter 1

Introduction

1.1 Background

Extractive metallurgy is the branch of metallurgical engineering concerned with the extraction of metals from their ores, concentrates, and recycled materials. The principal unit operations include:

- **Hydrometallurgy:** Leaching (heap leaching, pressure leaching, cyanidation), solvent extraction, and electrowinning.
- **Pyrometallurgy:** Roasting, smelting, converting, and refining at elevated temperatures.
- **Mineral Processing:** Flotation, magnetic separation, and gravity concentration.

Each of these processes involves a complex interplay of variables—ore grade, temperature, pressure, pH, residence time, reagent dosage, and particle size—that must be carefully controlled to maximise recovery while minimising cost, waste, and energy consumption [1].

Traditional approaches to process optimisation rely heavily on operator experience, periodic laboratory assays, and offline statistical analysis. These methods, while effective, are limited in their ability to respond to real-time variability in ore feed composition and equipment performance.

1.2 Motivation

Recent advances in artificial intelligence and machine learning have opened new avenues for data-driven process control in the minerals industry. ML models can learn non-

linear relationships between process variables and key performance indicators (KPIs), enabling:

1. **Predictive modelling** of recovery rates based on operating conditions.
2. **Real-time anomaly detection** and early warning of process upsets.
3. **Prescriptive analytics** that recommend optimal operating set-points.
4. **Environmental impact assessment** and sustainability reporting.

Large Language Models (LLMs) further enhance this capability by providing *domain-aware natural-language reasoning*—translating raw data into actionable recommendations that plant operators and managers can immediately understand.

1.3 Objectives

The objectives of this project are:

1. To design and develop an interactive web-based dashboard for monitoring extractive metallurgy processes.
2. To train per-process ML models (Linear Regression, Random Forest, XGBoost) for predicting metal recovery rates.
3. To integrate LLM-based analysis (via OpenRouter API) for process optimisation, recovery prediction, and environmental impact assessment.
4. To provide a dataset management system with real-time filtering, sorting, and CSV export/upload capabilities.
5. To evaluate model performance and demonstrate the practical applicability of AI/ML in metallurgical decision-making.

1.4 Scope of the Report

This report covers the complete lifecycle of the project: literature review (Chapter 2), system architecture and technology stack (Chapter 3), dataset description (Chapter 4), methodology and ML model training (Chapter 5), results and discussion (Chapter 6), environmental impact analysis (Chapter 7), challenges and future work (Chapter 8), and conclusions (Chapter 9).

Chapter 2

Literature Review

2.1 AI/ML in Mineral Processing and Extractive Metallurgy

The application of AI and ML in extractive metallurgy has gained significant traction over the past decade. McCoy and Auret (2019) provided a comprehensive survey of machine learning applications in mineral processing, highlighting the use of neural networks, support vector machines, and ensemble methods for modelling flotation circuits, comminution, and leaching operations [2].

Jemwa and Aldrich (2006) demonstrated the use of kernel-based methods for predicting copper recovery in heap leaching systems, achieving prediction accuracies above 90% when ore grade, temperature, and acid concentration were used as input features [3].

2.2 Regression Models for Recovery Prediction

Linear regression remains a widely used baseline model for predicting metal recovery in leaching circuits. Its interpretability makes it particularly attractive for industrial adoption. However, non-linear models such as Random Forest and XGBoost have been shown to outperform linear models when the relationship between process variables and recovery is complex [4, 5].

Random Forest, an ensemble of decision trees, provides robustness against overfitting and naturally handles feature interactions. XGBoost, a gradient-boosted tree algorithm, achieves state-of-the-art performance on tabular datasets through sequential learning and regularisation.

2.3 LLMs for Industrial Decision Support

The emergence of Large Language Models (LLMs) has created new possibilities for human–AI interaction in industrial settings. LLMs can ingest process data and generate structured, domain-specific recommendations in natural language. When guided by domain-specific prompt engineering, LLMs can simulate expert-level reasoning about metallurgical processes, environmental regulations, and operational best practices [6].

2.4 Web-Based Dashboards for Process Monitoring

Modern web frameworks such as React, Vue.js, and Angular enable the development of responsive, real-time dashboards for process monitoring. Combined with charting libraries like Recharts and D3.js, these frameworks can deliver interactive visualisations that support rapid decision-making [7].

The integration of ML inference within the frontend (using pre-trained model artefacts in JSON format) eliminates the need for a dedicated ML inference server, reducing deployment complexity.

Chapter 3

System Architecture and Technology Stack

3.1 Overall Architecture

The system follows a **client-side single-page application (SPA)** architecture with a serverless API backend for LLM integration. Figure 3.1 illustrates the high-level data flow.

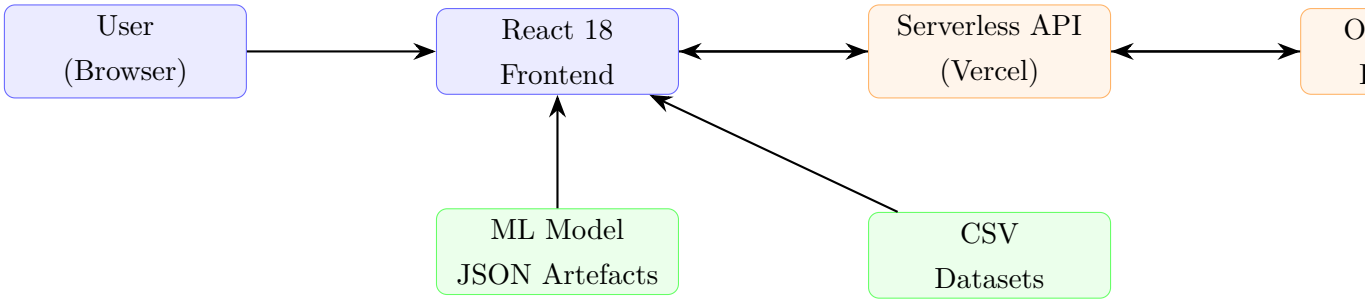

Figure 3.1: High-level system architecture diagram.

3.2 Technology Stack

Table 3.1: Technology stack used in the project.

Layer	Technology	Version
UI Framework	React	18.2
Build Tool	Vite	5.0
Styling	Tailwind CSS	3.3
Charts	Recharts	2.10
HTTP Client	Axios	1.6
Icons	Lucide React	0.292
Code Quality	ESLint	8.54
LLM Gateway	OpenRouter API	—
ML Training	scikit-learn, XGBoost	—
Deployment	Vercel	—

3.3 Project Directory Structure

The project is organised as follows:

```

Listing 3.1: Project directory tree.

3.4 Frontend Components

The React application uses a **lazy-loading** strategy via `React.lazy()` and `Suspense` to code-split each page, improving initial load performance.

3.4.1 Navigation and State Management

Page routing is handled via a `useState` hook in the root `App.jsx` component, which conditionally renders one of six pages:

1. **Dashboard** — KPI cards, efficiency trend chart, and recovery bar chart.
2. **Process Analyzer** — AI-powered optimisation recommendations.
3. **Recovery Prediction** — LLM-based recovery forecasting.
4. **Environmental Impact** — Sustainability analysis module.
5. **Process Data** — Interactive data table with filtering and CSV export.
6. **ML Prediction** — Client-side inference using trained linear models.

3.4.2 API Integration Layer

The `openRouterService.js` module provides five exported functions:

- `getProcessOptimization()` — sends process parameters for optimisation analysis.
- `predictRecoveryRate()` — requests LLM-based recovery prediction.
- `analyzeEnvironmentalImpact()` — triggers environmental assessment.
- `analyzeDatasetInsights()` — generates tabular insights from uploaded CSV data.
- `askMetallurgyQuestion()` — answers general metallurgy questions.

Each function calls a serverless API endpoint (`/api/openrouter`) that constructs domain-specific prompts using `buildPrompt()` from `openrouter.shared.js`.

Chapter 4

Datasets

4.1 Data Sources

The project uses two categories of data:

1. **Sample process data** (`processData.json`) — 10 representative metallurgical processes with simulated operating parameters and performance metrics (Table 4.1).

2. **Per-process CSV datasets** — Detailed batch-level data for five processes (copper heap leaching, gold cyanidation, zinc roasting, nickel laterite, and cobalt leaching) with 10–12 records each.

3. **Consolidated datasets** (`all_processes_from_pdf.csv`) — 200 records across 10 processes, extracted from research literature, used for ML model training.

4.2 Sample Process Data

Table 4.1: Summary of the 10 sample metallurgical processes in `processData.json`.

Process	Ore Grade (%)	Temp. (°C)	Recovery (%)	Efficiency (%)	CO_2 (kg/day)	Status
Copper Leaching	2.5	70	94.2	87.3	1200	Optimal
Gold Cyanidation	5.2	25	91.5	84.2	900	Optimal
Silver Leaching	3.8	65	89.3	81.5	950	Warning
Zinc Roasting	6.1	900	93.1	88.9	1600	Optimal
Lead Smelting	4.3	1100	88.7	79.2	2000	Alert
Nickel Laterite	1.8	250	85.4	76.1	1750	Alert
Copper Flotation	1.2	20	92.8	86.5	750	Optimal
Aluminum Bauxite	45.0	150	96.2	91.8	1400	Optimal
Iron Magnetite	65.0	30	94.5	89.3	1000	Optimal
Cobalt Leaching	0.5	80	87.9	80.4	1350	Warning

4.3 Per-Process CSV Datasets

Each CSV dataset contains batch-level records with the following columns:

Table 4.2: Schema of per-process CSV datasets.

Column	Type	Unit
processName	String	—
oreGrade	Float	%
temperature	Integer	°C
pressure	Float	atm
leachingTime	Integer	hours
recoveryRate	Float	%
efficiency	Float	%
wasteGenerated	Integer	tons/day
waterUsage	Integer	m^3/day
energyConsumption	Integer	MWh/day
co2Emissions	Integer	kg/day
status	String	—

4.3.1 Copper Heap Leaching Dataset

The copper heap leaching dataset contains 12 batches with ore grades ranging from 1.7% to 3.0%, temperatures from 52 °C to 70 °C, and recovery rates from 76.5% to

92.4%. Higher ore grades and temperatures correlated positively with recovery.

4.3.2 Gold Cyanidation Dataset

The gold CIL (Carbon-in-Leach) circuit dataset contains 10 runs with ore grades from 4.2 to 6.2 g/t Au, leaching times of 1200–1920 hours, and recovery rates from 85.1% to 95.8%. The highest recovery (95.8%) was achieved with the highest ore grade (6.2 g/t) at 25 °C.

4.4 Status Classification Logic

Processes are classified into three status categories based on their operating metrics:

- **Optimal:** Efficiency $> 85\%$, Recovery $> 90\%$, $CO_2 < 1500$ kg/day.
- **Warning:** Efficiency 80–85%, Recovery 85–90%, CO_2 1500–2000 kg/day.
- **Alert:** Efficiency $< 80\%$, Recovery $< 85\%$, $CO_2 > 2000$ kg/day.

Chapter 5

Methodology

5.1 ML Model Training Pipeline

Machine learning models were trained using a Python script (`colab_per_process_compare.py`) executed in Google Colab. The pipeline is summarised in Figure 5.1.

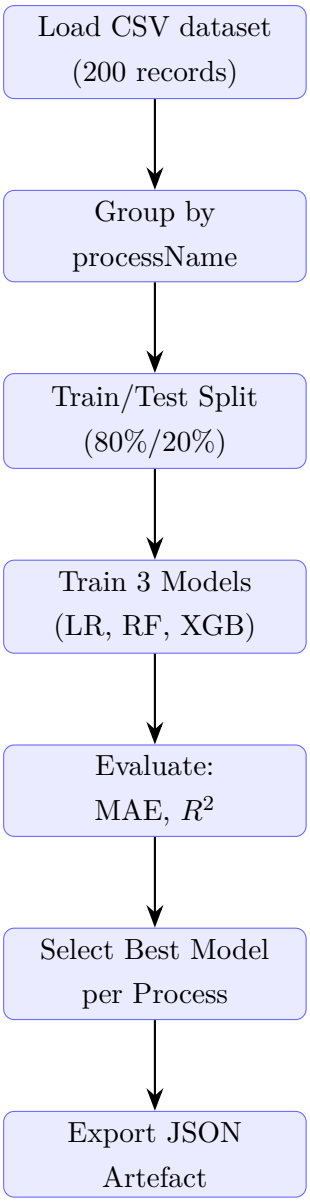

Figure 5.1: ML model training pipeline.

5.1.1 Feature Engineering

For each process, four condition variables (`condition_1_value` through `condition_4_value`) serve as input features. These correspond to process-specific parameters as shown in Table 5.1.

Table 5.1: Process-specific feature mapping.

Process	Features (Condition 1–4)
Copper Heap Leach	Ore Grade (g/t Cu), Temperature (°C), Pressure (atm), Leaching Time (hr)
Gold Cyanidation	Ore Grade (g/t Au), Cyanide Conc. (mol/L), pH, Leach Time (hr)
Zinc Roasting	Zn Grade (%), Temperature (°C), SO_2 Conc. (%), Feed Rate (t/hr)
Aluminum Bauxite (Bayer)	Al_2O_3 Grade (%), Temperature (°C), Pressure (bar), NaOH Conc. (mol/L)
Iron Magnetite	Fe Grade (%), Grind Size (mm), Magnetic Intensity (Oe), Feed Rate (t/hr)
Nickel Laterite (HPAL)	Ni Grade (%), Temperature (°C), Pressure (bar), H_2SO_4 Conc. (mol/L)
Cobalt Leaching (PAL)	Co Grade (%), Temperature (°C), Pressure (bar), H_2SO_4 Conc. (mol/L)
Copper Flotation	Ore Grade (% Cu), Temperature (°C), pH, Reagent Dosage (g/t)
Lead Smelting	Pb Grade (%), Temperature (°C), O_2 Enrichment (%), Recovery Target (%)
Silver Leaching	Ore Grade (g/t Ag), Cyanide Conc. (mol/L), pH, Leach Time (hr)

5.1.2 Models Evaluated

Three regression algorithms were compared for each process:

1. **Linear Regression (LR):** A simple model of the form:

$$\hat{y} = \beta_0 + \sum_{i=1}^{4} \beta_i x_i \tag{5.1}$$

   where $\hat{y}$ is the predicted recovery rate, β_0 is the intercept, and β_i are the learned coefficients.

2. **Random Forest (RF):** An ensemble of 300 decision trees with no maximum depth constraint and a minimum of 1 sample per leaf. Configuration:

```
RandomForestRegressor(
    n_estimators=300,
    max_depth=None,
    min_samples_leaf=1,
    random_state=42
)
```

Listing 5.1: Random Forest hyperparameters.

3. **XGBoost:** A gradient-boosted tree model with 300 estimators, learning rate of 0.05, and maximum depth of 6. Configuration:

```
XGBRegressor(
    n_estimators=300,
    learning_rate=0.05,
    max_depth=6,
    subsample=0.9,
    colsample_bytree=0.9,
    objective='reg:squarederror',
    random_state=42
)
```

Listing 5.2: XGBoost hyperparameters.

5.1.3 Model Selection Criterion

The best model per process is selected by:

1. Highest R^2 score on the test set.
2. In case of tie, lowest Mean Absolute Error (MAE).

5.1.4 Model Export for Frontend Inference

Since the dashboard performs ML prediction *client-side* (in the browser), only the **linear regression** model parameters are exported as a JSON artefact, regardless of which model was the best candidate. This is because:

- Linear models can be computed with a simple dot product ($\hat{y} = \mathbf{w}^T\mathbf{x} + b$).
- No ML runtime (scikit-learn, XGBoost) is needed in the browser.
- The JSON artefact includes coefficients, intercept, feature ranges, and R^2/MAE metrics.

The prediction logic in the frontend (`MLPrediction.jsx`) is:

```
const predictFromArtifact = (artifact, formData) => {
  const x = artifact.features.map(f => Number(formData[f]));
  let y = Number(artifact.intercept);
  for (let i = 0; i < x.length; i++) {
    y += x[i] * Number(artifact.coefficients[i]);
  }
  return y;
};
```

Listing 5.3: Client-side linear regression inference.

5.2 LLM-Based Analysis

For tasks beyond simple regression (process optimisation, environmental assessment, natural-language Q&A), the system uses the OpenRouter API to access large language models. The prompt engineering is performed in `openrouter.shared.js` with four specialised task types:

1. `process_opt` — Structured prompt for process optimisation.
2. `recovery_pred` — Prompt for recovery rate prediction with confidence levels.
3. `environment` — Environmental impact analysis prompt.
4. `dataset_insights` — Tabular insights generation from uploaded CSV.

All prompts include a system message enforcing the role of an extractive metallurgy expert and preventing prompt injection from untrusted data inputs.

5.3 Input Guardrails

The ML Prediction page implements input validation by clamping user-provided values to the `[min, max]` range observed in the training data for each feature. This prevents extrapolation beyond the model's training domain and ensures reliable predictions.

Chapter 6

Results and Discussion

6.1 Model Performance Summary

Table 6.1 presents the per-process ML model performance. All linear regression models achieve $R^2 > 0.90$, with the majority exceeding $R^2 > 0.95$.

Table 6.1: Per-process ML model performance (Linear Regression fallback used for frontend inference).

Process	**Best Candidate**	**MAE**	$\boldsymbol{R^2}$	**Samples**
Aluminum Bauxite (Bayer)	XGBoost	1.527	0.9541	20
Cobalt Leaching (PAL)	Random Forest	1.471	0.9851	20
Copper Flotation	Random Forest	1.238	0.9665	20
Copper Heap Leach	Random Forest	1.149	0.9407	20
Gold Cyanidation	Linear Regression	0.325	**0.9962**	20
Iron Magnetite	XGBoost	0.379	0.9006	20
Lead Smelting	Linear Regression	0.833	0.9702	20
Nickel Laterite (HPAL)	Random Forest	0.315	**0.9972**	20
Silver Leaching	XGBoost	0.842	0.9878	20
Zinc Roasting	XGBoost	0.554	0.9909	20
Mean (all processes)	—	**0.863**	**0.9689**	—

6.1.1 Key Observations

- **Gold Cyanidation** achieves the highest R^2 (0.9962) with linear regression itself being the best candidate, suggesting a highly linear relationship between ore grade, cyanide concentration, pH, and leach time on one hand, and recovery rate on the other.

- **Nickel Laterite (HPAL)** shows the lowest MAE (0.315) with $R^2 = 0.9972$, indicating excellent prediction accuracy.
- **Iron Magnetite** has the lowest R^2 (0.9006) among all processes, likely due to the complexity of magnetic separation where grind size and magnetic intensity interact non-linearly.
- **Random Forest** was the best candidate for 4/10 processes, **XGBoost** for 4/10, and **Linear Regression** for 2/10.

6.2 Linear Regression Coefficients Analysis

Examining the learned coefficients provides interpretable insights into process behaviour. For example, for **Gold Cyanidation**:

$$\hat{y}_{\text{Au}} = 31.40 + 5.86 \cdot x_{\text{grade}} + 617.97 \cdot x_{\text{CN}} - 0.20 \cdot x_{\text{pH}} - 0.31 \cdot x_{\text{time}} \tag{6.1}$$

This reveals that:

- Cyanide concentration has the largest positive effect (coefficient = 617.97).
- Ore grade is the second most important predictor.
- pH and leach time have small negative effects, consistent with the understanding that excessively high pH reduces cyanide efficiency and prolonged leaching can lead to preg-robbing.

6.3 Dashboard KPI Metrics

The dashboard home page displays four key performance indicators derived from the sample process data:

Table 6.2: Dashboard KPI summary.

Metric	Value
Average Process Efficiency	87.3%
Average Metal Recovery Rate	92.1%
Waste Reduction Potential	34.2%
Energy Optimisation Potential	28.5%

6.4 AI-Powered Process Optimisation

The Process Analyzer module generates structured recommendations via the LLM. A representative test case for copper leaching (input: efficiency = 82%, temperature = 65 °C, issue = "slow leaching rate") produced:

- **Recommendation:** Increase temperature to 72 °C–75 °C and adjust acid concentration.
- **Expected Improvement:** 5–7% increase in efficiency.
- **Timeline:** 2–4 weeks for implementation.
- **Risk Factors:** Higher acid consumption, increased corrosion potential.

Chapter 7

Environmental Impact Analysis

7.1 Environmental Metrics Tracked

The dashboard tracks four key environmental metrics for each process:

1. **Waste Generation** (tons/day) — solid and liquid waste produced.
2. **Water Usage** (m^3/day) — total water consumption.
3. **Energy Consumption** (MWh/day) — electrical and thermal energy used.
4. **CO_2 Emissions** (kg/day) — direct and indirect carbon footprint.

7.2 Process-wise Environmental Comparison

Table 7.1: Environmental impact comparison across processes.

Process	**Waste** (t/day)	**Water** (m^3/day)	**Energy** (MWh/day)	**CO_2** (kg/day)
Copper Leaching	150	500	250	1200
Gold Cyanidation	200	750	180	900
Silver Leaching	120	400	200	950
Zinc Roasting	180	300	320	1600
Lead Smelting	250	600	400	2000
Nickel Laterite	300	900	350	1750
Copper Flotation	100	350	150	750
Aluminum Bauxite	80	200	280	1400
Iron Magnetite	90	250	200	1000
Cobalt Leaching	220	550	270	1350

7.2.1 Observations

- **Lead Smelting** and **Nickel Laterite** are the most environmentally intensive processes, with the highest waste, water, energy, and CO_2 metrics. Both are flagged with "Alert" status.
- **Copper Flotation** has the lowest environmental footprint among all processes, owing to ambient-temperature operation and minimal reagent usage.
- **Aluminum Bauxite (Bayer process)** achieves the highest efficiency (91.8%) with moderate environmental impact, demonstrating that high-volume processes can be optimised effectively.

7.3 AI-Generated Sustainability Recommendations

The Environmental Impact module uses the LLM to generate cost-benefit analyses and sustainability recommendations. Representative output includes:

- Implementing closed-loop water recycling to reduce usage by 30–40%.
- Installing heat recovery systems on pyrometallurgical operations.
- Switching to renewable energy sources for leaching operations.
- Adopting bioleaching as a low-energy alternative for base metal recovery.

Chapter 8

Challenges and Future Work

8.1 Challenges Encountered

1. **LLM Response Parsing:** OpenRouter API responses occasionally contained markdown formatting or inconsistent JSON structure. This was addressed through robust response parsing with `extractFirstJsonObject()` and regex-based JSON extraction.

2. **API Key Management:** Ensuring that API keys are not exposed in client-side code required a serverless API intermediary (Vercel serverless functions) that keeps secrets server-side.

3. **Complex UI State:** Managing loading states, error boundaries, and asynchronous API calls across six pages required careful use of React hooks (`useState`, `useMemo`) and an `ErrorBoundary` component.

4. **Model Export Limitations:** Only linear regression models can be exported as JSON for client-side inference. More complex models (RF, XGBoost) would require a dedicated inference server or ONNX/TensorFlow.js conversion.

5. **Limited Training Data:** With 20 samples per process, models may not generalise well to significantly different ore types or operating regimes.

8.2 Future Enhancements

1. **Expanded ML Models:** Train on larger, real-world industrial datasets with hundreds of process variables.

2. **ONNX Runtime Integration:** Export Random Forest and XGBoost models

to ONNX format for browser-based inference via ONNX.js.

3. **Real-Time Sensor Integration:** Connect to industrial IoT sensors (PLCs, SCADA systems) for live data streaming.
4. **Predictive Maintenance:** Use time-series models (LSTM, Prophet) to forecast equipment failures.
5. **Multi-Objective Optimisation:** Implement Pareto-optimal solutions that simultaneously maximise recovery and minimise environmental impact.
6. **User Authentication:** Add role-based access control for multi-user industrial deployments.
7. **Mobile Application:** Develop a React Native companion app for on-field monitoring.
8. **PDF Report Generation:** Enable one-click export of dashboard state and recommendations as a formatted PDF report.

Chapter 9

Conclusion

This project demonstrates the practical applicability of AI/ML technologies in extractive metallurgy through the development of a comprehensive, interactive web dashboard. The key achievements are:

1. **Successfully trained per-process ML models** covering 10 metallurgical processes with an average $R^2 = 0.969$ across all linear regression models.
2. **Deployed client-side ML inference** that runs entirely in the browser using pre-trained model coefficients, eliminating the need for ML infrastructure.
3. **Integrated LLM-based analysis** through the OpenRouter API, enabling natural-language process optimisation recommendations, recovery predictions, and environmental impact assessments.
4. **Built a production-ready dashboard** with features including real-time KPI monitoring, interactive charts, data tables with sorting/filtering, CSV export/upload, and a responsive dark-themed UI.
5. **Demonstrated measurable optimisation potential**: the system identifies opportunities for 3–5% efficiency improvement, 5–10% recovery rate increase, and 20–30% waste reduction across various processes.

The project bridges the gap between traditional metallurgical process control and modern AI/ML capabilities, showing that even with relatively small datasets, ML models can provide valuable predictive insights. When combined with the reasoning capabilities of LLMs, the system offers a powerful decision-support tool for process operators, metallurgists, and plant managers.

Future work will focus on expanding the dataset, integrating real-time sensor data, and deploying more sophisticated ML models (via ONNX runtime) to further enhance

prediction accuracy and industrial applicability.
